Chapter 6

Shiqi YU 于仕琪

yusq@sustech.edu.cn

6.1 Ordering

Shiqi Yu 于仕琪 yusq@sustech.edu.cn

order by

There is one simple expression in SQL to order a result set, which is ORDER BY. It comes at the end of a query (although you can have it in subqueries, as you'll see). It is followed by the list of columns used as sort columns.

This will return all movies, starting with the oldest one.

select title, year_released
from movies
order by year_released

Sorts the result of the query

table unchanged

select title, year_released
from movies
where country = 'us'
order by year_released

We can apply it to any result set ...

```
select m.title,
      m.year_released
from movies m
where m.movieid in
  (select distinct c.movieid
   from credits c
        inner join people p
        on p.peopleid = c.peopleid
  where c.credited_as = 'A'
    and p.birth_year >= 1970)
order by m.year_released
```

... no matter how complicated the query.

```
select c.country_name,
      m.title,
      m.year_released
from movies m
     inner join countries c
     on c.country_code = m.country
where m.movieid in
  (select distinct c.movieid
   from credits c
        inner join people p
       on p.peopleid = c.peopleid
  where c.credited_as = 'A'
     and p.birth_year >= 1970)
order by m.year_released
```

and with joins you can sort by any column of any table in the join (remember the super wide table with all the columns from all tables involved)

order by col1 desc, col2 asc, ...

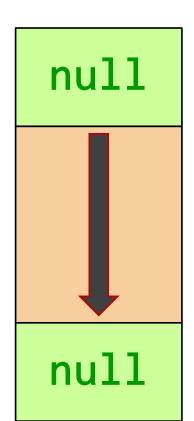

You can specify that a sort is descending by following the column name with DESC. You can also use ASC to say ascending, but as it's the default nobody uses it.

```
select c.country_name,
      m.title,
      m.year_released
from movies m
    inner join countries c
    on c.country_code = m.country
where m.movieid in
  (select distinct c.movieid
  from credits c
       inner join people p
       on p.peopleid = c.peopleid
  where c.credited_as = 'A'
    and p.birth_year >= 1970)
order by c.country_name,
        m.year_released desc, m.title
```

ordering depends on the data type

Remember that strings are sorted alphabetically, numbers numerically and dates and times chronologically. What happens when data is missing?

NULLs?

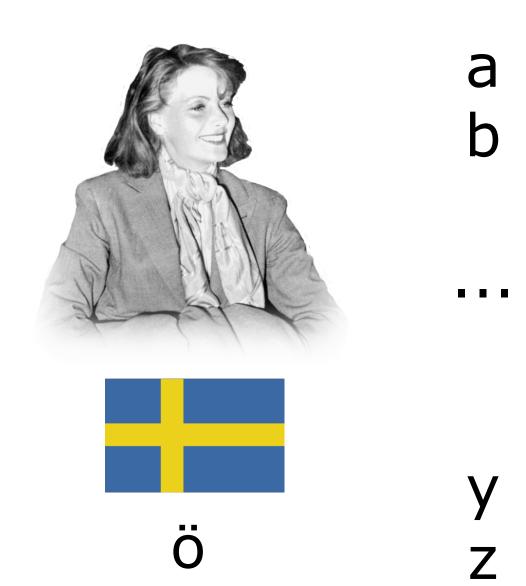

It depends on the DBMS. SQL Server, MySQL and SQLite consider by default that nothing is smaller than everything, and DB2, Oracle and PostgreSQL that it's greater than anything. Don't believe that things are simple with text, either. They are relatively simple in English, as long as you don't use a foreign word with an accent such as attaché.

In this case, you would probably think that é should sort with e (so do I), but that's not necessarily what internal encoding says. Besides, local habits may vary. Swedes think that ö should come after z. German speakers rather see it with o (Swedish is the default language for MySQL)

Local text sorting rules are known as "collations". Some products allow you to specify how data in a column should be sorted when you create the table. It's also sometimes possible to specify how you want data to be sorted when you do it.

Collation

```
some_text_column varchar(100)
 collate <collation name> not null,
...)
```

```
order by nls_sort(some_text_column,
                  '<collation name>')
```

create table ... (

How are Chinese text strings sorted?

How many collations can you choose for Chinese?

I've told you that usually dates are converted to a user-friendly format when returned, for instance with TO_CHAR() available in several products.

But if you sort by this column (text) the sort will be alphabetical! You should sort by the original, date column:

```
order by a_date_column
```

You can sort by a column that isn't returned.

movies

movied	title	country	year_released
1832	Gone With The Wi	ind us	1939

For instance suppose that we add producers to the movie database (credited_as = 'P')

credits

movied	peopleid	credited_as
1832	237	Α
1832	312	Α
1832	742	Р
1832	128	D

people

peopleid	first_name	surname	born died
237	Clark	Gable	1901 1960
742	David	Selznick	1902 1965
312	Vivien	Leigh	1913 1967
128	Victor	Fleming	1889 1949

If we want to sort people by function first, with the director first, producer second and actors last ...

Director Producer Actors

Actors

Director

Producer

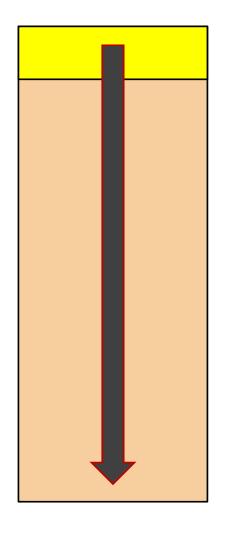

... no matter whether CREDITED_AS is ascending or descending, sorting by it won't work.

order by credited_as desc

Director Producer Actors

order by
 case credited_as
 when 'D' then 1
 when 'P' then 2
 when 'A' then 3
 end

The solution is to use CASE ... END to replace each code with a value that sorts as intended. This is frequently used for "custom sorts".

Three oldest?

order by year_released

Another problem that isn't so easy is displaying only a limited number of oldest values, or successive "slices" in a long sorted list.

Top 10

title ▼ c	ountry	year_released
Annie Hall	us	1977
Blade Runner	us	1982
Bronenosets Potyomkin	ru	1925
Casablanca	us	1942
Citizen Kane	us	1941
Das Boot	de	1985
Det sjunde inseglet	se	1957
Doctor Zhivago	us	1965
Goodfellas	us	1990
Il buono, il brutto, il cattivo	o it	1966

1 2 3 4

Successive pages are common on websites. Here titles are sorted.

Skip 10, Top 10

title ▼	country	year_released
Inglourious Basterds	us	2009
Jaws	us	1975
La Belle et la Bête	fr	1946
Ladri di biciclette	it	1948
Lawrence of Arabia	gb	1962
Le cinquième élément	fr	1997
Les Visiteurs du Soir	fr	1942
Mary Poppins	us	1964
On The Waterfront	us	1954
Pather Panchali	in	1955

1 2 3 4

First Page

limit 10

Several products implement a LIMIT clause that is executed AFTER the sort; this syntax seems to be gaining in popularity.

First Page

select title, country, ORACLE year_released **PostgreSQL** from movies order by title fetch first 10 rows only

DB2 has something slightly different, which was also (more recently) adopted by Oracle and Postgres.

First Page

```
select top 10
       title,
       country,
       year_released
from movies
order by title
```

SQL Server is frankly different, but the logic is the same: you sort, then discard everything but what you want.

Third Page

select title, country, year_released

from movies order by title limit 10 offset 20

Retrieving rows 20 to 30 in a sorted result is easy with PostgreSQL, MySQL and SQLite.

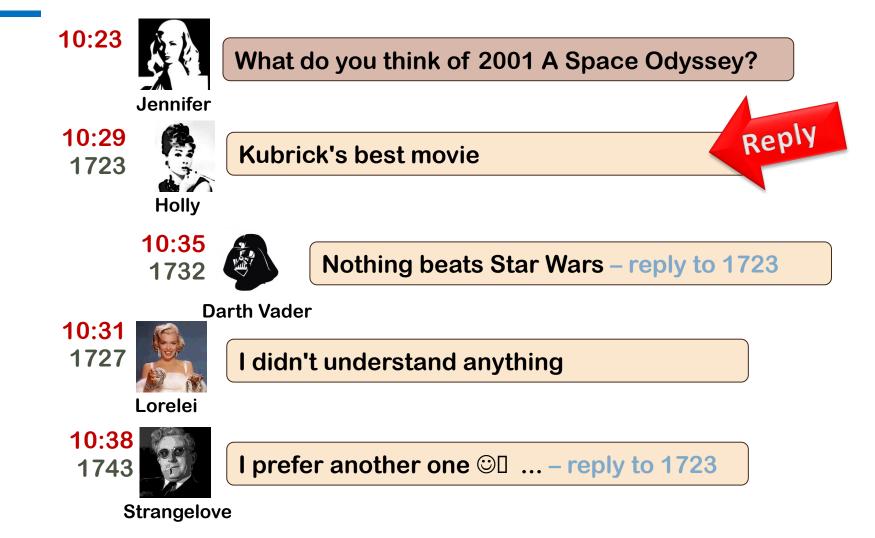

Third Page select title, country, ORACLE" year_released PostgreSQL from movies order by title offset 20 fetch first 10 rows only

What when order is a bit more subtle?

There are many cases when plain ordering isn't satisfying.

Such a case is a forum. Somebody posts a topic, then people post their comments in sequence. Things turn ugly when somebody starts posting an answer to a comment rather than to the original topic. Some forums always keep a sequential order and force users to add say @Holly or @1723 (the post id) to help others understand what they are reacting at.

A better solution (for visitors, not developers) is to maintain "threads"

10:23 What do you think of 2001 A Space Odyssey? **Jennifer** 10:29 **Kubrick's best movie** 1723 Holly Reply 10:35 **Nothing beats Star Wars – reply to 1723** 1732 **Darth Vader** 10:38 I prefer another one ©□ ... – reply to 1723 1743 **Strangelove** 10:31 1727 I didn't understand anything Lorelei 10:36 Are you kidding? – reply to 1732 1733 **Harry Lime**

But threads can develop into complicated hierarchies.

10:23 **Jennifer** 10:29 1723 Holly

What do you think of 2001 A Space Odyssey?

Kubrick's best movie

10:35 1732

Nothing beats Star Wars – reply to 1723

Reply

Darth Vader

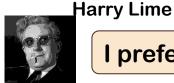

10:36 1733

Strangelove

10:31 1727

I didn't understand anything

Lorelei

10:40 1747

Darth, you'll stop trolling if I ask you gently. reply to 1732

Nobody's perfect, and the area where SQL database management systems struggle a bit is the management of hierarchies (sometimes referred to as the BOM problem – Bill Of Materials). This is something you encounter everywhere you have to deal with items that can be divided in subitems that can also be subdivided and indefinite number of times. A few example:

- * Cars, made of components that can themselves have subcomponents
- * Chemistry. Ingredients rarely are "pure" ingredients but already the result of chemical processes
- * Financial participations. You can have parts in two companies, one of which also has parts in the other (also known as "financial exposure")

10:23

What do you think of 2001 A Space Odyssey?

10:29 1723

NULL

10:35 1732

000001723

Darth Vader

10:36 1733

000001723000001732

10:40 1747

000001723000001732

10:38 1743

000001723

Strangelove

10:31 1727

NULL

One way to try to solve the problem is the "materialized path", turning the "ancestry" into an attribute.

Lorelei

ORACLE®

```
select message, ....
from forum_posts ...
connect by answered_postid = prior postid
start with answered_postid is null
    and topicid = ...
order siblings by postid
thef
```

Oracle has long (since the first half of the 1980s) implemented a way to refer to a 'prior row' in a kind of "dynamic ordering" Most products handle hierarchies through recursive queries, that we'll see in some detail next time.

6.2 Window Functions

Shiqi Yu 于仕琪 yusq@sustech.edu.cn Another very important (but not available in MySQL before 8 or SQLite) set of functions for ordering/reporting are window functions. They bear different names, Oracle calls them analytic functions, DB2 calls them OLAP (OnLine Analytical Processing) functions. They are of two kinds, we'll start with non-ranking functions.

Non-ranking Window Functions

Ranking

We have seen so far two categories of functions: functions that operate on values in the current row (called scalar functions), and aggregate functions, that operate on sets of rows.

Year of oldest movie per country?

The problem with aggregate functions is that details just vanish. If I ask for the year of the oldest movie per country, I get a country, a year, and nothing else.

TILE and year of the

earliest movie per country

If I want some detail, for instance which was the title of this oldest movie, the only option with aggregate functions is to join their output to the very same table that has been aggregated to retrieve the lost detail.

For instance, by joining with movies I can retrieve the title(s) of the movie(s) released in this country that year. Intuitively, we feel that we visited **MOVIES** twice and that perhaps we could have done better.

```
select a.country,
      a.title,
       a.year_released
from movies a
     inner join
     (select country,
        min(year_released) minyear
        from movies
        group by country) b
  on b.country = a.country
   and b.minyear = a.year_released
```

Window functions hold the middle-ground between scalar and aggregate functions. Like scalar functions, they return a result for a single row; but like aggregate functions, this result is computed out of several rows. The syntax is as follows

func (parameters) over (magic clause)

With DBMS products that support window functions, every aggregate function can be used as a window function. Instead of specifying with GROUP BY the subset on which the result is computed, you say OVER (PARTITION BY ...)

min(year_released)
 over (partition by country)

Thus, this query returns two years for every movie: the one when this particular movie was released, and the one when the earliest movie for the same country was released. You get both detail and an aggregate value on the same row.

TILE and year of the

earliest movie per country

country	title	year_released	earliest_year
am	Sayat Nova	1969	1969
ar	La Ciénaga	2001	1945
ar	La bestia debe morir	1952	1945

ar	La hora de los hornos	1968	1945
ar	El abrazo partido	2004	1945
ar	Hombre mirando al sudeste	1986	1945
ar	Crónica de una fuga	2006	1945
ar	Las aventuras del Capitán Piluso	1963	1945
ar	Albéniz	1947	1945

```
select m.country,
       m.title,
       m.year_released
from (select country,
             title,
             year_released,
             min(year_released)
              over (partition by country)
                      earliest_year
      from movies) m
where m.year_released = m.earliest_year
```

You just need to limit output to those movies for which the year of release happens to be the same as the earliest one for their country.

     from movies
```

If you filter out, with a WHERE condition, one movie, it will be excluded from the window function computation. The earliest year may become the second earliest.

from movies
 where title <> 'A title here') m
where m.year_released = m.earliest_year

Window functions always operate against rows that belong to a result set. One related characteristics is that they can only appear after the SELECT, not in the WHERE clause, and there is nothing with them similar to HAVING with aggregate functions (it's not a real limitation; you can always work around it by wrapping the query into another one that applies conditions to its output, as shown previously)

Reporting function

SELECTED rows

```
select a.country, a.title, a.year_released
from movies a
    inner join
    (select country,
           min(year_released) earliest_year
     from movies
    where title <> 'A title here'
    group by country) b
       on b.country = a.country
      and b.earliest_year = a.year_released
```

We have seen the functional equivalence with GROUP BY + join, the previous example works like what is above, with the minimum computed on everything but one movie.

```
select m.country, m.title,
              m.year_released
      from
        (select country,
                 title,
                 year_released,
                 min(year_released)
                 over (partition by country)
                               earliest_year
            from movies) m
      where m.year_released = m.earliest_year
        and title <> 'A title here'
If the query is nested, then the minimum is computed over everything,
then filtered out. One country may disappear out of the picture.
```

```
select a.country, a.title, a.year_released
from movies a
     inner join
    (select country,
           min(year_released) earliest_year
     from movies
    group by country) b
       on b.country = a.country
      and b.earliest_year = a.year_released
where a.title <> 'A title here'
```

This query is functionally equivalent to the previous one.

min(year_released) over()

In the same way that you can have an aggregate function without a GROUP BY when you want ONE result for the whole table, you can have an empty OVER clause to indicate that you want the result computed over all rows selected. Note that OVER () is still mandatory otherwise the function would be interpreted as a regular aggregate function, not as a window function.

```
select country_name,
       cnt as number_of_movies,
       round(100 * cnt / sum(cnt) over (), 0)
                  as percentage
from (select c.country_name,
             coalesce(m.cnt, 0) cnt
      from countries c
           left outer join (select country,
                                   count(*) cnt
                            from movies
                            group by country) m
                  on m.country = c.country_code
) q
order by country_name
```

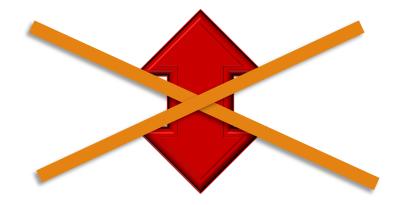

This is frequently used in operations such as computing a value as a percentage of the total.

Side note: when there is an ORDER BY you cannot start returning rows before you have seen all of them - so you may count them too when sorting, and the marginal cost of the window function is near zero.

```
select country_name,
                 cnt as number_of_movies,
                 round(100 * cnt / t.movie_count, 0) percentage
          from (select c.country_name,
                       coalesce(m.cnt, 0) cnt
                from countries c
                     left outer join (select country,
                                             count(*) cnt
                                      from movies
                                      group by country) m
                            on m.country = c.country_code
          ) q
               cross join (select count(*) movie_count
                           from movies) t
          order by country_name
The same thing can be obtained with a type of join we haven't seen yet,
a CROSS JOIN (without any join condition, also called a Cartesian join)
```

If all aggregate functions can be used as window functions, there are also some window functions that provide ranking capabilities. These functions are original functions and unrelated to either aggregate functions or scalar functions. There are a few of them, we'll only discuss the most important ones.

ranking window function

aggregate function

func() over (...)

When we talk about "ranking", of course, we implicitly talk about "ordering". In the same way as we can put into the OVER clause how we group, we can also say there how we order.

There are three main ranking functions. In many cases, they return identical values. Differences are interesting.

```
row_number()
rank()
dense_rank()
```

With a ranking window function you MUST have an ORDER BY clause in the OVER() (you cannot have an empty OVER() clause). You can combine it with a PARTITION BY to order with groups.

id	title	country	year_released
1	Casablanca	us	1942
2	Blade Runner	us	1982
3	On The Waterfront	us	1954
4	Lawrence Of Arabia	gb	1962
5	Annie Hall	us	1977
6	Goodfellas	us	1990
7	The Third Man	gb	1949
8	Citizen Kane	us	1941
9	Bicycle Thieves	it	1948
10	The Battleship Potemki	in ru	1925
11	Sholay	in	1975
12	A Better Tomorrow	hk	1986

id	title	country	year_released
1	Casablanca	us	1942 5
2	Blade Runner	us	1982 2
3	On The Waterfront	us	1954 4
4	Lawrence Of Arabia	gb	1962 1
5	Annie Hall	us	1977 3
6	Goodfellas	us	1990 1
7	The Third Man	gb	1949 2
8	Citizen Kane	us	1941 6
9	Bicycle Thieves	it	1948 1
10	The Battleship Potemk:	in ru	1925 1
11	Sholay	in	1975 1
12	A Better Tomorrow	hk	1986

```
select title,
    country,
    year_released,
    row_number()
    over ( partition by country
        order by year_released desc) rn
```

from movies

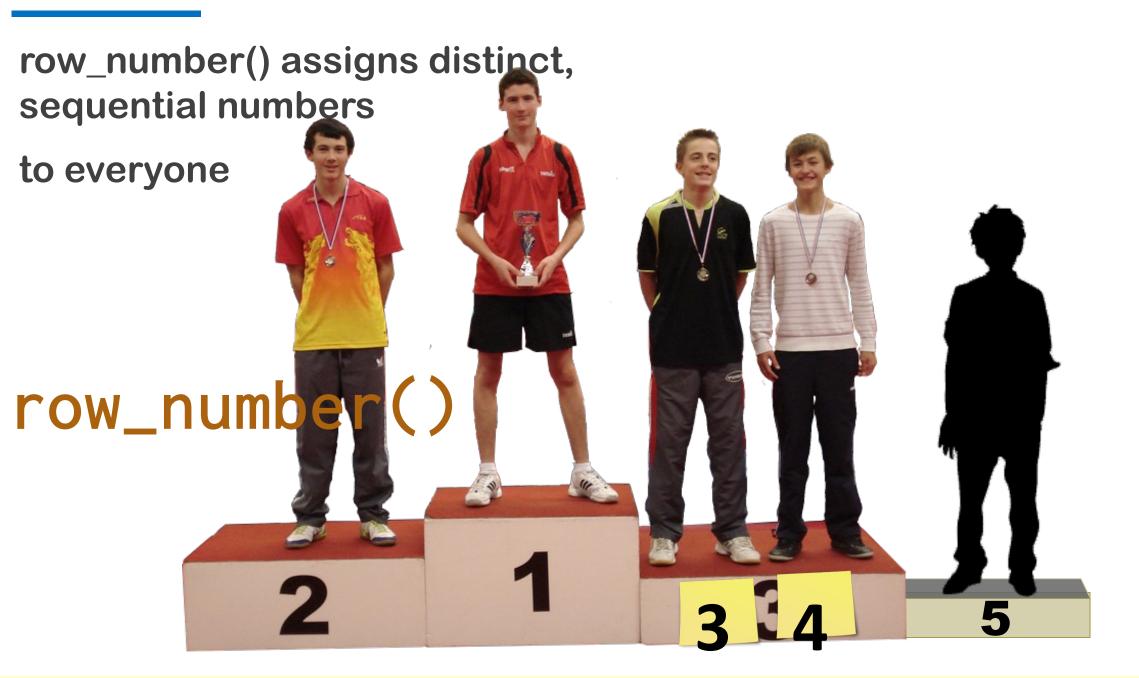

In this example, movies are grouped by country, and a sequential number is assigned by country to each movie, starting with the most recent movie.

title	country	year_released
Casablanca	us	1942
Blade Runner	us	1982
On The Waterfront	us	1954
Lawrence Of Arabia	gb	1962
Annie Hall	us	1977
Goodfellas	us	1990
The Third Man	gb	1949
Citizen Kane	us	1941
Bicycle Thieves	it	1948
The Battleship Potemki	n ru	1925
Sholay	in	1975
A Better Tomorrow	hk	1986

over (partition by col1, col2, ... order by col3, col4, ...)

As with plain GROUP BY and plain ORDER BY, both partitioning and ordering can be applied to several columns (and "columns" can of course be expressions).

rank() assigns the same number to ties, but there is a gap in ranks. rank()

Which are the **two most recent** movies for each country?

As an aside, a condition on ROW_NUMBER() works a bit like LIMIT applied to ORDER BY, except that ordering can be by group.

Ranking window functions allow answering easily some really tough questions which are almost impossible to answer efficiently otherwise.

```
select x.country,
      x.title,
      x.year_released
from
(select country,
        title,
        year_released,
        row_number()
        over (partition by country
              order by year_released desc) rn
from movies ) x
where x.rn \le 2
```
