# C/C++ Program Design

**LAB** 10

## **CONTENTS**

- Learn cmake
- Learn the concept of storage duration, scope and linkage
- Learn to use namespaces

# 2 Knowledge Points

- 2.1 Cmake
- 2.2 Storage duration, Scope and Linkage
- 2.3 Namespaces

## 2.1 CMake

## What is CMake?

Cmake is an open-source, cross-platform family of tools designed to build, test and package software. Cmake is used to control the software compilation process using simple platform and compiler independent configuration files, and generate native makefiles and workspaces that can be used in the compiler environment of your choice.

CMake needs CMakeLists.txt to run properly.

A CMakeLists.txt consists of **commands**, **comments** and **spaces**.

- The commands include command name, brackets and parameters, the parameters are separated by spaces. Commands are not case sensitive.
- Comments begins with '#'.

Steps for generating a makefile and compiling on Linux using Cmake:

**Step1**: Writes the CMake configuration file **CMakeLists.txt**.

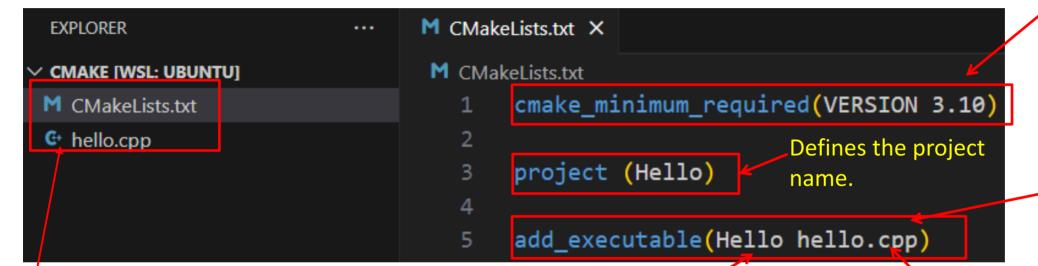

Step2: Executes the command cmake PATH to generate the Makefile. (PATH is the directory where the CMakeLists.txt resides.)

**Step3**: Compiles using the **make** command.

## 1. A single source file in a project

The most basic project is an executable built from source code files. For simple

projects, a three-line CMakeLists.txt file is all that is required.

Specifies the minimum required version of CMake.

Use **cmake --version** in Vscode terminal window to check the cmake version in your computer.

Adds the Hello executable target which will be built from hello.cpp.

The first parameter indicates the filename of executable file.

The second parameter indicates the source file.

Store the CMakeLists.txt file in the same directory as the hello.cpp.

Suppose there is a hello.cpp

In current directory, type cmake. to generate makefile. If cmake does not be installed, follow the instruction to intall cmake.

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake$ cmake .
 Command 'cmake' not found, but can be installed with:
 sudo apt install cmake
                       Install cmake first by instruction
 $ sudo apt install cmake
  [sudo] password for maydlee:
  Reading package lists... Done
  Building dependency tree
  Reading state information... Done
  The following additional packages will be installed:
    cmake-data libjsoncpp1 librhash0
  Suggested packages:
    cmake-doc ninja-build
  The following NEW packages will be installed:
    cmake cmake-data libjsoncpp1 librhash0
  0 upgraded, 4 newly installed, 0 to remove and 151 not upgraded.
  Need to get 5470 kB of archives.
  After this operation, 28.3 MB of additional disk space will be used.
  Do you want to continue? [Y/n]
```

#### maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake\$ cmake .

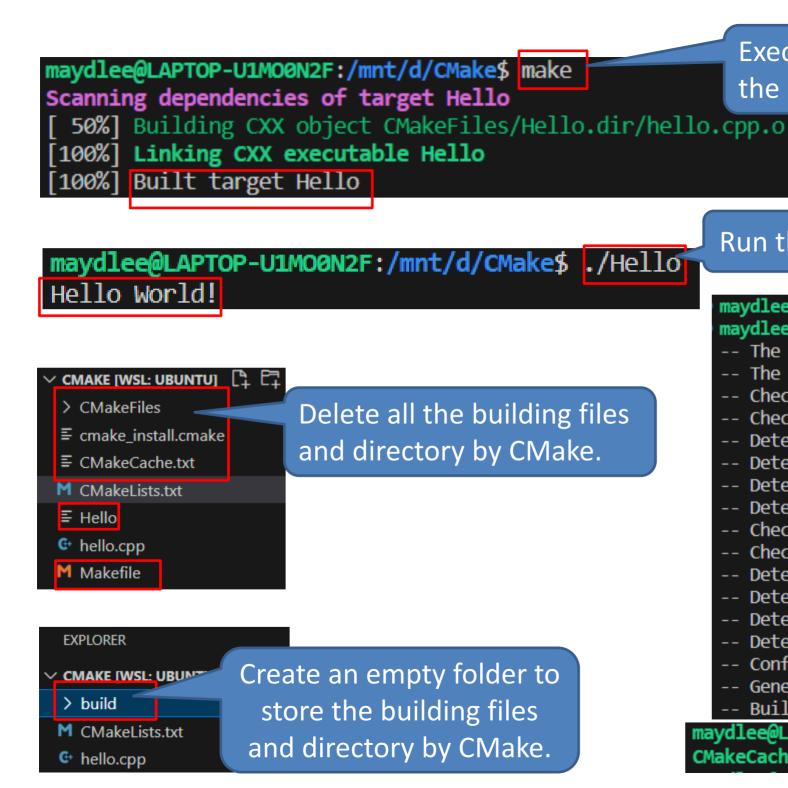

- -- The C compiler identification is GNU 9.4.0

maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ ls
```

Makefile cmake install.cmake

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ cmake --build .
Scanning dependencies of target Hello
[ 50%] Building CXX object CMakeFiles/Hello.dir/hello.cpp.o
[100%] Linking CXX executable Hello
[100%] Built target Hello
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ ls
CMakeCache.txt CMakeFiles Hello Makefile cmake_install.cmake
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ ./Hello
Hello World!
```

#### or

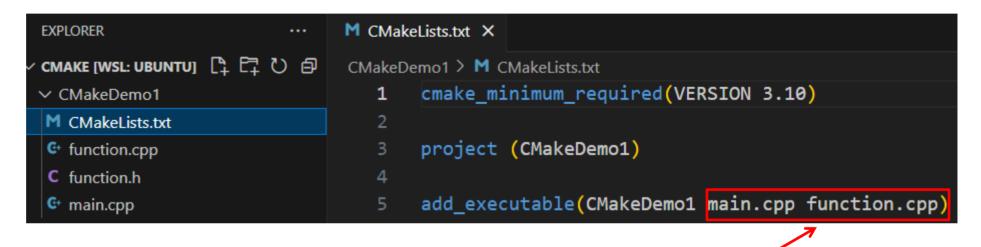

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ make
Scanning dependencies of target Hello
[ 50%] Building CXX object CMakeFiles/Hello.dir/hello.cpp.o
[100%] Linking CXX executable Hello
[100%] Built target Hello
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ ls
CMakeCache.txt CMakeFiles Hello Makefile cmake_install.cmake
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/build$ ./Hello
Hello World!
```

## 2. Multi-source files in a project

There are three files in the same directory.

```
./CmakeDemo1

|
+--- main.cpp
|
+--- function.cpp
|
+--- function.h
```

List all the source files using space as the separator.

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake$ cd CMakeDemo1
                                                                  Create a folder
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo1$ mkdir build <
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo1$ cd build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo1/build$ cmake ...
-- The C compiler identification is GNU 9.4.0
-- The CXX compiler identification is GNU 9.4.0

[ 66%] Building CXX object CMakeFiles/CMakeDemo1.dir/function.cpp.o
[100%] Linking CXX executable CMakeDemo1
[100%] Built target CMakeDemo1
```

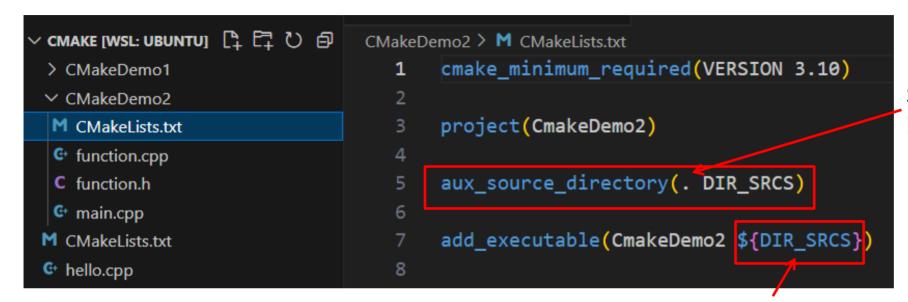

## 2. Multi-source files in a project

If there are several files in directory, put each file into the add\_executable command is not recommended. The better way is using aux\_source\_directory command.

aux\_source\_directory (<dir> <variable>)

The command finds all the source files in the specified directory indicated by <dir> and stores the results in the specified variable indicated by <variable>.

## 2. Multi-source files in a project

Store all files in the current directory into DIR\_SRCS variable.

Compile the source files in the variable by \${ } into an executable file named CmakeDemo2

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake$ cd CMakeDemo2
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo2$ mkdir build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo2$ cd build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo2/build$ cmake ...
-- The C compiler identification is GNU 9.4.0
-- The CXX compiler identification is GNU 9.4.0
-- Check for working C compiler: /usr/bin/cc
-- Check for working C compiler: /usr/bin/cc -- works
-- Detecting C compiler ABI info
-- Detecting C compiler ABI info - done
-- Detecting C compile features
-- Detecting C compile features - done
-- Check for working CXX compiler: /usr/bin/c++

-- Detecting CXX compiler ABI info - done
-- Detecting CXX compile features
-- Detecting CXX compile features - done
-- Configuring done
-- Generating done
-- Build files have been written to: /mnt/d/CMake/CMakeDemo3/build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo3/build$ make
Scanning dependencies of target CMakeDemo3
 33%] Building CXX object CMakeFiles/CMakeDemo3.dir/src/function.cpp.o
 66%] Building CXX object CMakeFiles/CMakeDemo3.dir/src/main.cpp.o
[100%] Linking CXX executable CMakeDemo3
[100%] Built target CMakeDemo3
```

# 4. Static library Dynamic library

We want to create a static(or dynamic) library by function.cpp and call the static(or dynamic) library in main.cpp. This time we write two CMakeLists.txt files, one in CmakeDemo4 folder and another in lib folder.

The CMakeLists.txt in lib folder creates a static library.

```
./CMakeDemo4
|
+--- main.cpp
|
+--- lib/
|
+--- function.h
|
+--- function.cpp
```

```
∨ CMAKE [WSL: UBUNTU] 📮 🛱 ひ 🗗
                                CMakeDemo4 > lib > M CMakeLists.txt
 > CMakeDemo1
                                        # Search the source files in the current directory
 > CMakeDemo2
                                        # and store them into the variable LIB_SRCS
 > CMakeDemo3
                                        aux source directory(. LIB SRCS)

∨ CMakeDemo4

  ∨ lib
  M CMakeLists.txt
                                        # Create a static library
                                        add_library(MyFunction(STATIC)${LIB_SRCS})
  G function.cpp
  C function.h
  M CMakeLists.txt
  @ main.cpp
                                      library file name
                                                                        The directory from which
                                                         static library
                                                                        the library file originates.
```

Create a static library named libMyFunction.a by the files in the current directory.

**Note**: If we use **SHARED** instead of STATIC in **add\_library** command, it will create a shared(dynamic) library file.

#### The CMakeLists.txt in CMakeDemo4 folder creates the project.

```
V CMAKE [WSL: UBUNTU] [+ □ □ □
                               CMakeDemo4 > M CMakeLists.txt
                                      # CMake minimum version
 > CMakeDemo1
                                       cmake minimum required(VERSION 3.10)
 > CMakeDemo2
 > CMakeDemo3
                                       # project information

∨ CMakeDemo4

                                       project(CMakeDemo4)

✓ lib

  M CMakeLists.txt
                                       # Search the source files in the current directory
   G function.cpp
                                       # and store them into the variable DIR SRCS
   C function.h
 M CMakeLists.txt
                                       aux source directory(. DIR SRCS)
                                 10
  @ main.cpp
M CMakeLists.txt
                                 11
                                       # add the directory of include
                                       include directories(lib)
 G hello.cpp
                                 12
                                 13
                                      # add the subdirectory of lib
                                 14
                                       add subdirectory(lib)
                                 15
add_subdirectory command
indicates there is a subdirectory
                                       # Specify the build target
in the project. When running the 18
                                       add executable(CMakeDemo4 ${DIR SRCS})
command, it will execute the
                                 19
CMakeLists.txt in the subdirectory
                                      # Add the static library
                                      target_link_libraries (CMakeDemo4) (MyFunction)
automatically.
                                 21
```

Indicates that the project needs link a library named **MyFunction**, MyFunction can be a static library file or a dynamic library file.

project name

library file name

If there are more than one file, list them using space as the separator.

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo4\ mkdir build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo4$ cd build
maydlee@LAPTOP-U1MO0N2F:/mnt/d/CMake/CMakeDemo4/buildg cmake ...

  50%] Built target myrunction
Scanning dependencies of target CMakeDemo4
  75%] Building CXX object CMakeFiles/CMakeDemo4.dir/main.cpp.o
```

[100%] Linking CXX executable CMakeDemo4

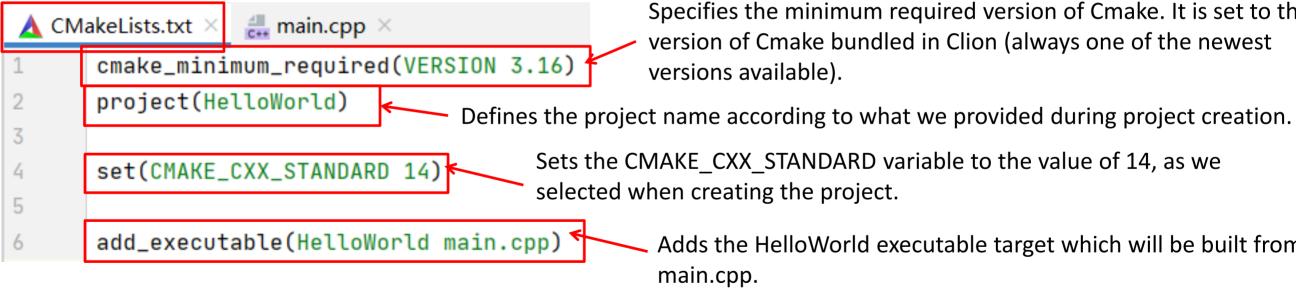

[100%] Built target CMakeDemo4

If we use **SHARED** in add\_library command, there will creates a dynamic library named **libMyFunction.so** and link with it in main.

### Create a C++ project by CLion, the CMakeLists.txt is created automatically.

Specifies the minimum required version of Cmake. It is set to the version of Cmake bundled in Clion (always one of the newest versions available).

Sets the CMAKE CXX STANDARD variable to the value of 14, as we selected when creating the project.

> Adds the HelloWorld executable target which will be built from main.cpp.

# 2.2 Storage duration, Scope and Linkage

- Scope describes the region or regions of a program that can access an identifier. An
  identifier has one of following scopes: block scope, function prototype scope, or file scope.
- Linkage describes how a name can be shared in different units. A variable has one of the following linkages: external linkage, internal linkage, or no linkage. A name with external linkage can be shared across files, and a name with internal linkage can be shared by functions within a single file. Names of automatic variables have no linkage because they are not shared.
- Storage duration describes the lifetime of a variable. A variable has one of the following storage durations: automatic storage duration, static storage duration, dynamic storage duration or thread storage duration.

C++ uses three separate schemes(four under C++11) for storing data. The different storage classes offer different combinations of scope, linkage and storage duration.

- Automatic storage duration: Variables declared inside a function definition (including function parameters) have automatic storage duration. They are created when program execution enters the function or block in which they are defined, and the memory used for them is freed when execution leaves the function or block.
- Static storage duration: Variables defined outside a function definition or else by using the keyword static have static storage duration. They persist for the entire time a program is running.
- Dynamic storage duration: Memory allocated by the new operator persists until it is freed with the delete operator or until the program ends, whichever comes first. This memory has dynamic storage duration and sometimes is termed the free store or the heap.
- Thread storage duration(C++11): Variables declared with the thread\_local keyword have storage that persists for as long as the containing thread lasts.

#### 2.2.1 Automatic Storage Duration

Function parameters and variables declared inside a function have, by default, automatic storage duration. They also have local scope and no linkage.

```
G autoduration.cpp > ...
     #include <iostream>
     using namespace std;
     int main()
         int x = 30; // original x
         cout << "x in outer block: " << x << " at " << &x << endl;</pre>
 8
            int x = 77; // new x, hide the original x
10
            cout << "x in inner block: " << x << " at " << &x << endl;</pre>
11
12
         cout << "x in outer block: " << x << " at " << &x << endl;</pre>
13
                                                                         x in outer block: 30 at 0x7ffe1da7d240
14
                                                                        x in inner block: 77 at 0x7ffe1da7d244
         while(x++ < 33) // original x</pre>
15
                                                                         x in outer block: 30 at 0x7ffe1da7d240
16
            int x = 100; // new x, hide the original x
17
                                                                        x in while loop: 101 at 0x7ffe1da7d244
18
            X++;
                                                                        x in while loop: 101 at 0x7ffe1da7d244
            cout << "x in while loop: " << x << " at " << &x << endl;</pre>
19
                                                                        x in while loop: 101 at 0x7ffe1da7d244
20
         cout << "x in outer block: " << x << " at " << &x << endl;</pre>
21
                                                                        x in outer block: 34 at 0x7ffe1da7d240
22
23
         return 0;
24
```

#### 2.2.2 Static Storage Duration

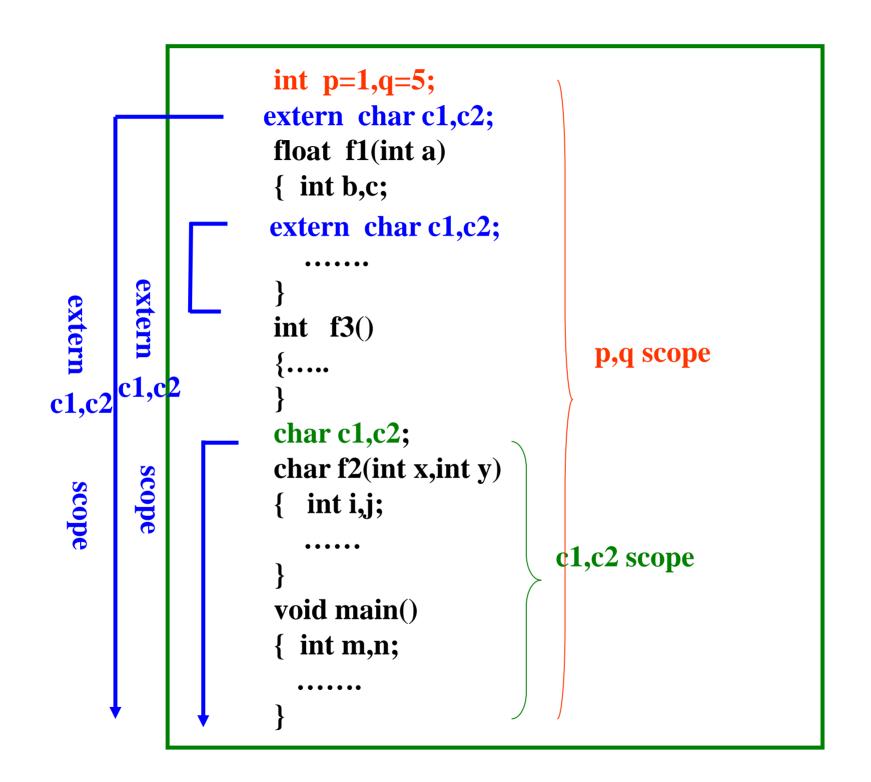

C++, like C, provides **static storage duration variables** with three kinds of linkage: **external linkage** (accessible across files), **internal linkage** (accessible to functions within a single file), and **no linkage** (accessible to just one function or to one block within a function).

All three last for the duration of the program. The static variables stay present as long as the program executes.

#### 1. Static Duration, External Linkage

Variables with **external linkage** are often simply called **external variables**(**global variables**). They necessarily have static storage duration and file scope. External variables are defined outside, and hence external to any function.

If you use an external variable in several files, only one file can contain a definition for that variable (per the one definition rule). But every other file using the variable needs to declare that variable using the keyword extern.

```
#include <iostream>
using namespace std;
              Declare a global variable whose initial value is 0
int x;
∃int
     main()
                          Declare a local variable whose name is
                             the same as the global variable.
    int x = 256;
                                                     The local variable hides the global variable.
     cout << "local variable x = " << x << endl;
     cout << "global variable x = " << ::x << endl;</pre>
                                                  Using scope-resolution operator(::)
     return 0;
                                                      to access the global variable.
```

local variable x = 256 global variable x = 0

#### 2. Static Duration, Internal Linkage

Variables of this storage class have static storage duration, file scope, and internal linkage. You can create one by defining it outside of any function (just as with an external variables) with the storage class specifier static. A variable with internal linkage is local to the file that contains it.

```
file1
                          // external declaration
   int errors = 20;
     file2
                            ??known to file2 only??
   int errors = 5;
   void froobish()
                                                                         external variable
                          // fails
         cout << errors;
                                                        file1
                                                                                external declaration
                                                      int errors = 20
Using static to share data among functions
   found in just one file, avoiding name
                                                      // file2
                                                      static int errors = 5; // known to file2 only
     conflicting with external variable.
                                                      void froobish()
                                                                             // uses errors defined in file2
                                                           cout << errors:
```

#### 3. Static Duration, No Linkage

You create such a variable by applying the **static** modifier to a variable defined **inside a block**. When you use it inside a block, static causes a local variable to have static storage duration. If you initialize a static local variable, the program **initializes the variable once**.

```
#include <iostream>
      using namespace std;
     void trystat();
     int main()
          for(int count = 1; count <= 3; count++)</pre>
              cout << "Here comes iteration " << count << ":\n":</pre>
 10
              trystat();
 11
 12
 13
 14
          return 0;
 15
 16
 17
      void trystat()
                             auto variable
 18
          int fade = 1;
 19
                                    static variable
         static int stay = 1;
 20
 21
          cout << "fade = " << fade++ << " and stay = " << stay++ << endl;</pre>
 22
 23
```

```
Here comes iteration 1:
fade = 1 and stay = 1
Here comes iteration 2:
fade = 1 and stay = 2
Here comes iteration 3:
fade = 1 and stay = 3
```

```
G factorial.cpp > 分 factorial(int)
      #include <iostream>
      using namespace std;
  3
      long factorial(int n);
      int main()
          for(int i = 1; i <= 5; i++)
              cout << i << "!= " << factorial(i) << endl;</pre>
 10
11
          return 0;
12
13
      long factorial(int n)
14
15
          static long product = 1;
16
17
          product *= n;
18
19
20
          return product;
 21
```

C and C++ use scope, linkage, and storage duration to define five storage classes: automatic, register, static with block scope, static with external linkage, and static with internal linkage.

#### **Five Storage Classes**

Storage Class	Duration	Scope	Linkage	<b>How Declared</b>
automatic	Automatic	Block	None	In a block
register	Automatic	Block	None	In a block with the keyword register
static with external linkage	Static	File	External	Outside of all functions
static with internal linkage	Static	File	Internal	Outside of all functions with the keyword static
static with no linkage	Static	Block	None	In a block with the keyword static

```
e partb.cpp > ...
     #include <iostream>
     using namespace std;
     extern int count:
                         //reference declaration, external linkage
     static int total = 0; //static definition, internal linkage
      void accumulate(int n)
                             //n has block scope, no linkage
                                         static variable
          static int subtotal = 0; // scacic, no iinkage
 10
 11
          if(n \le 0)
 12
 13
 14
              cout << "loop cycle: " << count << endl;</pre>
              cout << "subtotal: " << subtotal << ", total: " << total << endl;</pre>
 15
              subtotal = 0;
 17
 18
          else
 19
              subtotal += n;
 20
 21
              total += n;
 22
```

```
maydlee@LAPTOP-U1MO0N2F:/mnt/d/mycode/CcodeVs/lab09_examples$ g++ parta.cpp partb.cpp
maydlee@LAPTOP-U1MO0N2F:/mnt/d/mycode/CcodeVs/lab09_examples$ ./a.out
Enter a positive integer(0 to quit):5
loop cycle: 1
subtotal: 15, total: 15
Enter a positive integer(0 to quit):10
loop cycle: 2
subtotal: 55, total: 70
Enter a positive integer(0 to quit):2
loop cycle: 3
subtotal: 3, total: 73
Enter a positive integer(0 to quit):0
Loop executed 3 times.
```

```
parta.cpp > ...
    #include <iostream>
     using namespace std:
     void report count();
     void accumulate(int n);
     int count = 0;  //file scope, external linkage
     int main()
         int value; //automatic variable
10
         register int i: //register variable
11
12
         cout << "Enter a positive integer(0 to quit):";</pre>
13
         while(cin >> value)
14
15
             if(value == 0)
17
                 break:
             if(value > 0)
18
                 ++count:
                 for(i = value; i >= 0; i--)
21
                     accumulate(i);
                                       Calling the function
22
23
                                          for several times
             cout << "Enter a positive integer(0 to quit):";</pre>
25
         report_count();
27
         return 0;
28
29
30
     void report count()
32
         cout << "Loop executed " << count << " times.\n";</pre>
34
```

## 2.3 Namespace

Namespaces provide a much more controlled mechanism for preventing name collisions. A namespace is a scope.

#### Namespace definition

```
namespace name

namespace nsp{
    // variables (with their initializations)
    // structure declaration
    // functions (with their definitions)
    // templates declaration
    // classes declaration
    // other namespaces
}
There is no semicolon.
```

```
This two variables are not conflict.
namespace Jack{
    double pail;
                            // variable declaration
   void fetch();
                         // function prototype
                         // variable declaration
   int pal;
    struct Wll{ /... };
                     // structure declaration
namespace Jill/{
    double bucket (double n) { ... } // function definition
   double fetch;
                                 // variable declaration
                                // variable declaration
   int pal;
    struct Hill{ ... }; // structure declaration
```

You can use ::, the scope-resolution operator, to qualify a name with its namespace.

```
Jack::pail = 12.34  // use a variable
Jill::Hill mole;  // create a type Hill structure
Jack::fetch();  // call a function
```

#### using Declarations and using Directives

A **using declaration** introduces only **one namespace member** at a time. Names introduced in a using declaration obey normal scope rules: they are visible from the point of the using declaration to the end of the scope in which the declaration appears. Entities with the same name defined in an outer scope are hidden.

```
variable declared in namespace Jill
namespace Jill{
    double bucket (double n)
                                         function definition
    double fetch:
                                         variable declaration
                                         variable declaration
    int pal;
    struct Hill{ ... };
                                         structure declaration
                  global variable
char fetch:
                       Using declaration
int main()
    using Jill::fetch;
                                put fetch into local namespace
    double fetch;
                                Error! Already have a local fetch
    cin >> fetch;
                                read a value into Jill::fetch
    cin >> ::fetch;
                                read a value into global fetch
```

Placing a using declaration at the external level adds the name to the global namespace:

```
void other();
namespace Jill{
    double bucket(double n) { ... } // function definition
   double fetch;
                                // variable declaration
                                // variable declaration
   int pal;
   struct Hill{ ... }; // structure declaration
using Jill::fetch;
                            put fetch into global namespace
int main()
   cin >> fetch;  // read a value into Jill::fetch
   other();
void other()
   cout << fetch; // display Jill::fetch</pre>
    . . .
```

A **using declaration**, makes a single name available. In contrast, the **using directive** makes all the names available.

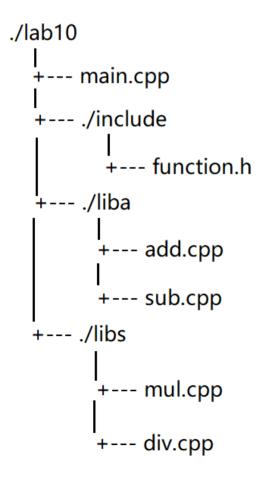

```
using namespace Jack; // make all the names in Jack available
#include <iostream>
                         // places names in namespace std
                           make names available globally
using namespace std;
int main()
    using namespace Jack; // make names available in main()
    . . .
```

Generally speaking, the using declaration is safer to use than a using directive because it shows exactly what names you are making available.

```
namespace sdm{
    const double BOOK_VERSION = 2.0;
    class Handle{...};
    Handle& getHandle();
void f1()
    using namespace sdm;
    cout << BOOK_VERSION; // OK</pre>
    Handle h = getHandle(); // OK
void f2()
   using sdm::BOOK_VERSION;
    cout << BOOK VERSION;
                              // OK
    Handle h = getHandle(); // Wrong
void f3()
    cout << sdm::BOOK_VERSION;</pre>
                                  // OK
    double d = BOOK VERSION;
                                 // Wrong
    Handle h = getHandle();
                                 // Wrong
```

## 3 Exercises

1.Define four functions that implement the operations of addition, subtraction, multiplication and division respectively.(one function one .cpp file) Write a test program to test these functions.

According to the tree structure of the files, creates a static library with the two files in the liba directory and a dynamic library with two files in the libs directory. And then link with main.cpp. Using cmake command to compile and build your project. At last run the program.

#### 2. Write a three-file program based on the following namespace:

```
namespace SALES
[
    const int QUATERS = 4;
    struct Sales
        double sales[QUATERS];
        double average;
        double max:
        double min;
    };
    // copies n items from the array ar to the sales member of s and
    // computes and stores the average, maximum and minimum values
    // of the entered items.
    void setSales(Sales& s, const double ar[], int n = 4);
    // display all information in the sales s
    void showSales(const Sales& s, int n = 4);
```

The **first file** should be a header file that contains the namespace. The **second file** should be a source code file that extends the namespace to provide definitions for the two prototyped functions. The **third file** should define a Sales object. It should use setSales() to provide values for the structure. And then it should display the contents of the structure by using showSales().

## A sample runs might look like this:

```
Input n:3
Please input 3 double values:123.5 9087.6 3452.1
Sales:123.5 9087.6 3452.1
Average:4221.07
Max:9087.6
Min:123.5
```

Input n:5 n is not correct. Aborted
